Goals for Lecture

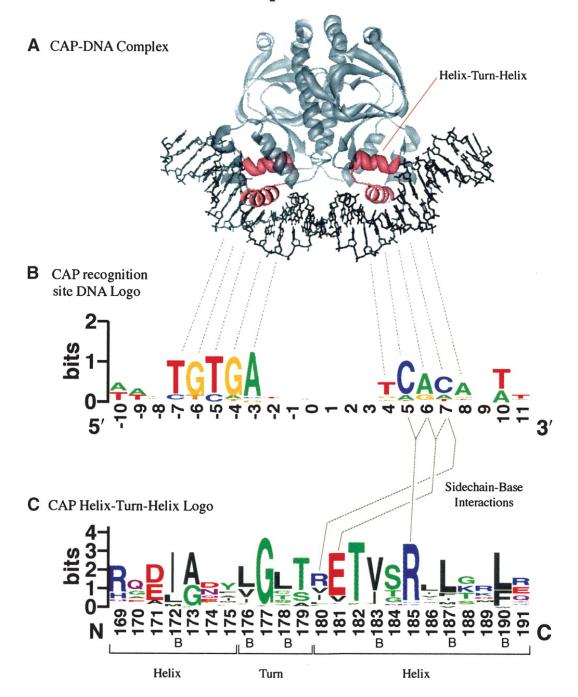

Key concepts

- the motif finding problem
- using EM to address the motif-finding problem
- the OOPS and ZOOPS models

Sequence Motifs

- What is a sequence motif?
 - a sequence pattern of biological significance
- Examples
 - DNA sequences corresponding to protein binding sites
 - protein sequences corresponding to common functions or conserved pieces of structure

Sequence Motifs Example

CAP-binding motif model based on 59 binding sites in E.coli

helix-turn-helix motif model based on 100 aligned protein sequences

Crooks et al., Genome Research 14:1188-90, 2004.

The Motif Model Learning Task

given: a set of sequences that are thought to contain occurrences of an unknown motif of interest

do:

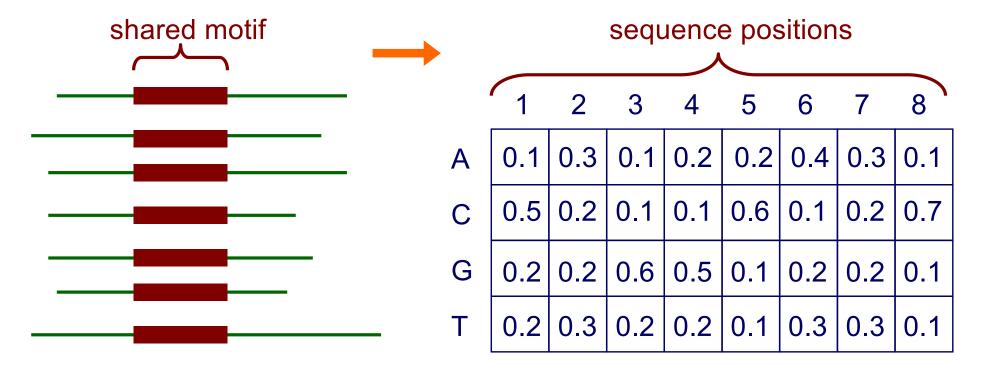

- infer a model of the motif
- predict the locations of the motif occurrences in the given sequences

Why is this important?

- To further our understanding of which regions of sequences are "functional"
- DNA: biochemical mechanisms by which the expression of genes are regulated
- Proteins: which regions of proteins interface with other molecules (e.g., DNA binding sites)
- Mutations in these regions may be significant

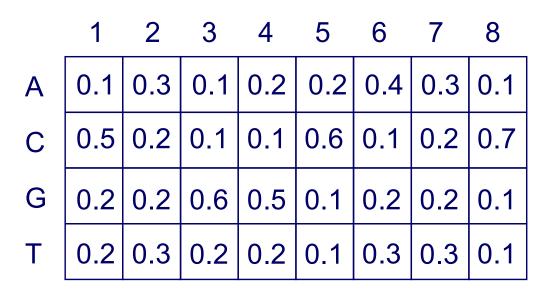

Motifs and *Profile Matrices* (a.k.a. *Position Weight Matrices*)

 Given a set of aligned sequences, it is straightforward to construct a profile matrix characterizing a motif of interest

 Each element represents the probability of given character at a specified position

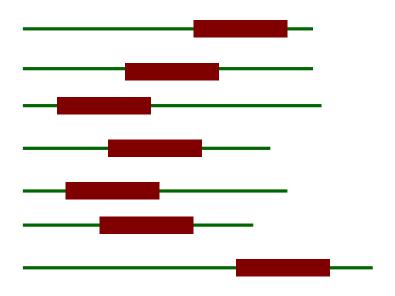

Sequence Logos

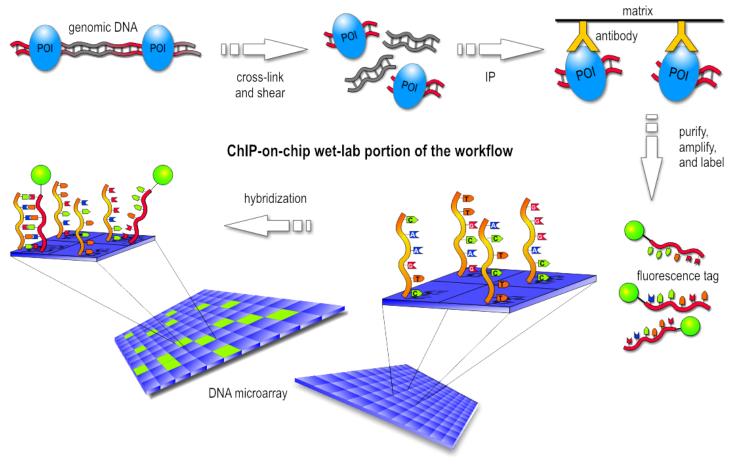

Motifs and Profile Matrices

- How can we construct the profile if the sequences aren't aligned?
- In the typical case we don't know what the motif looks like.

Unaligned Sequence Example

 ChIP-chip experiment tells which probes are bound (though this protocol has been replaced by ChIP-seq)

The Expectation-Maximization (EM) Approach

[Lawrence & Reilly, 1990; Bailey & Elkan, 1993, 1994, 1995]

- EM is a family of algorithms for learning probabilistic models in problems that involve hidden state
- In our problem, the hidden state is where the motif starts in each training sequence

Overview of EM

 Method for finding the maximum likelihood (ML) parameters (θ) for a model (M) and data (D)

$$\theta_{ML} = \operatorname*{argmax}_{\theta} P(D \mid \theta, M)$$

- Useful when
 - it is difficult to optimize $P(D | \theta)$ directly
 - likelihood can be decomposed by the introduction of hidden information (Z)

$$P(D \mid \theta) = \sum_{Z} P(D, Z \mid \theta)$$

- and it is easy to optimize the function (with respect to θ):

$$Q(\theta \mid \theta^t) = \sum_{Z} P(Z \mid D, \theta^t) \log P(D, Z \mid \theta)$$

Applying EM to the Motif Finding Problem

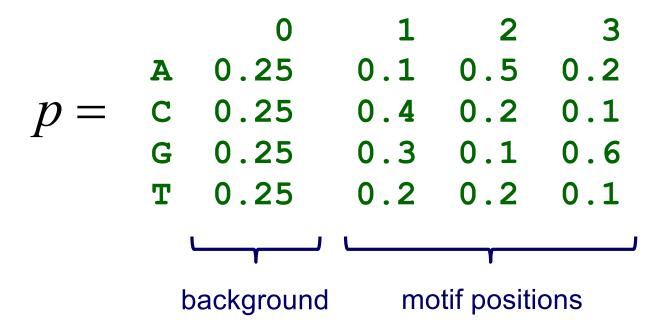

- First define the probabilistic model and likelihood function $P(D \mid \theta)$
- Identify the hidden variables (Z)
 - In this application, they are the locations of the motifs
- Write out the Expectation (E) step
 - Compute the expected values of the hidden variables given current parameter values
- Write out the Maximization (M) step
 - Determine the parameters that maximize the Q function, given the expected values of the hidden variables

Representing Motifs in MEME

- MEME: Multiple EM for Motif Elicitation
- A motif is
 - assumed to have a fixed width, W
 - represented by a matrix of probabilities: $p_{c,k}$ represents the probability of character c in column k
- Also represent the "background" (i.e. sequence outside the motif): $p_{c,\theta}$ represents the probability of character c in the background
- Data D is a collection of sequences, denoted X

Representing Motifs in MEME

Example: a motif model of length 3

Representing Motif Starting Positions in MEME

- The element $Z_{i,j}$ of the matrix Z is an indicator random variable that takes value 1 if the motif starts in position j in sequence i (and takes value 0 otherwise)
- Example: given DNA sequences where L=6 and W=3
- Possible starting positions m = L W + 1

	Z =				
		1	2	3	4
G T C A G G	seq1	0	0	1	0
G A G A G T	seq2	1	0	0	0
ACGGAG	seq3	0	0	0	1
CCAGTC	seq4	0	1	0	0

Probability of a Sequence Given a Motif Starting Position

$$P(X_i \mid Z_{i,j} = 1, p) = \prod_{k=1}^{j-1} p_{c_k,0} \prod_{k=j}^{j+W-1} p_{c_k,k-j+1} \prod_{k=j+W}^{L} p_{c_k,0}$$
 before motif motif after motif

 X_i is the i th sequence

 $Z_{i,j}$ is 1 if motif starts at position j in sequence i

 C_k is the character at position k in sequence i

Sequence Probability Example

 $0.25 \times 0.25 \times 0.2 \times 0.1 \times 0.1 \times 0.25 \times 0.25$

Likelihood Function

EM (indirectly) optimizes log likelihood of observed data

$$\log P(X \mid p)$$

M step requires joint log likelihood

$$\log P(X, Z \mid p) = \log \prod_{i} P(X_{i}, Z_{i} \mid p)$$

$$= \log \prod_{i} P(X_{i} \mid Z_{i}, p) P(Z_{i} \mid p)$$

$$= \log \prod_{i} \frac{1}{m} \prod_{j} P(X_{i} \mid Z_{i,j} = 1, p)^{Z_{i,j}}$$

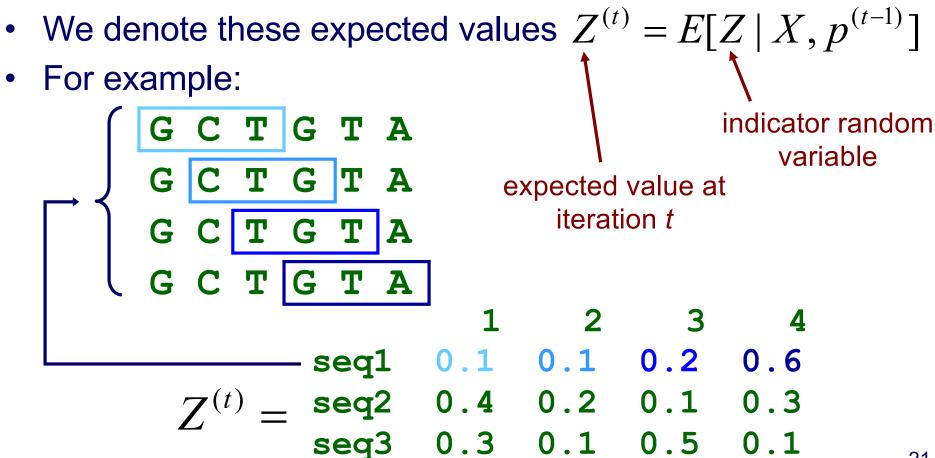

$$= \sum_{i} \sum_{j} Z_{i,j} \log P(X_{i} \mid Z_{i,j} = 1, p) + n \log \frac{1}{m}$$

Basic EM Approach

```
given: length parameter W, training set of sequences
    t=()
    set initial values for p^{(0)}
    do
         ++t
         re-estimate Z^{(t)} from p^{(t-1)}
                                                  (E-step)
         re-estimate p^{(t)} from Z^{(t)}
                                                  (M-step)
    until change in p^{(t)} < \varepsilon (or change in likelihood is < \varepsilon)
return: p^{(t)}, Z^{(t)}
```

Expected Starting Positions

 During the E-step, we compute the expected values of Z given X and $p^{(t-1)}$

The E-step: Computing $Z^{(t)}$

To estimate the starting positions in Z at step t

$$Z_{i,j}^{(t)} = \frac{P(X_i | Z_{i,j} = 1, p^{(t-1)})P(Z_{i,j} = 1)}{\sum_{k=1}^{m} P(X_i | Z_{i,k} = 1, p^{(t-1)})P(Z_{i,k} = 1)}$$

This comes from Bayes' rule applied to

$$P(Z_{i,j} = 1 | X_i, p^{(t-1)})$$

The E-step: Computing $Z^{(t)}$

 Assume that it is equally likely that the motif will start in any position

$$P(Z_{i,j}=1)=\frac{1}{m}$$

$$Z_{i,j}^{(t)} = \frac{P(X_i | Z_{i,j} = 1, p^{(t-1)})P(Z_{i,j} = 1)}{\sum_{k=1}^{m} P(X_i | Z_{i,k} = 1, p^{(t-1)})P(Z_{i,k} = 1)}$$

Example: Computing $Z^{(t)}$

$$X_i = G C T G T A G$$

$$p^{(t-1)} = egin{array}{ccccc} & 0 & 1 & 2 & 3 \\ A & 0.25 & 0.1 & 0.5 & 0.2 \\ C & 0.25 & 0.4 & 0.2 & 0.1 \\ G & 0.25 & 0.3 & 0.1 & 0.6 \\ T & 0.25 & 0.2 & 0.2 & 0.1 \\ \end{array}$$

$$Z^{(t)}_{i,1} \propto P(X_i | Z_{i,1} = 1, p^{(t-1)}) = 0.3 \times 0.2 \times 0.1 \times 0.25 \times 0.25 \times 0.25 \times 0.25$$

 $Z^{(t)}_{i,2} \propto P(X_i | Z_{i,2} = 1, p^{(t-1)}) = 0.25 \times 0.4 \times 0.2 \times 0.6 \times 0.25 \times 0.25 \times 0.25$

• Then normalize so that $\sum_{i=1}^{m} Z^{(t)}_{i,j} = 1$

The M-step: Estimating *p*

• Recall $p_{c,k}$ represents the probability of character c in position k; values for k=0 represent the background

$$p_{c,k}^{(t)} = \frac{n_{c,k} + d_{c,k}}{\sum_{b \in \{A,C,G,T\}}}$$
pseudo-counts

Example: Estimating p

ACAGCA

$$Z^{(t)}_{1,1} = 0.1, \ Z^{(t)}_{1,2} = 0.7, \ Z^{(t)}_{1,3} = 0.1, \ Z^{(t)}_{1,4} = 0.1$$

AGGCAG

$$Z^{(t)}_{2,1} = 0.4, \ Z^{(t)}_{2,2} = 0.1, \ Z^{(t)}_{2,3} = 0.1, \ Z^{(t)}_{2,4} = 0.4$$

TCAGTC

$$Z^{(t)}_{3,1} = 0.2, \ Z^{(t)}_{3,2} = 0.6, \ Z^{(t)}_{3,3} = 0.1, \ Z^{(t)}_{3,4} = 0.1$$

$$p^{(t)}_{A,1} = \frac{Z^{(t)}_{1,1} + Z^{(t)}_{1,3} + Z^{(t)}_{2,1} + Z^{(t)}_{3,3} + 1}{Z^{(t)}_{1,1} + Z^{(t)}_{1,2} \dots + Z^{(t)}_{3,3} + Z^{(t)}_{3,4} + 4}$$

$$p^{(t)}_{C,2} = \frac{Z^{(t)}_{1,1} + Z^{(t)}_{1,4} + Z^{(t)}_{2,3} + Z^{(t)}_{3,1} + 1}{Z^{(t)}_{1,1} + Z^{(t)}_{1,2} \dots + Z^{(t)}_{3,3} + Z^{(t)}_{3,4} + 4}$$

The ZOOPS Model

- The approach as we've outlined it, assumes that each sequence has exactly one motif occurrence per sequence; this is the OOPS model
- The ZOOPS model assumes <u>zero or one</u> occurrences per <u>sequence</u>

E-step in the ZOOPS Model

- We need to consider another alternative: the ith sequence doesn't contain the motif
- We add another parameter (and its relative)

$$\lambda = \frac{\gamma}{(L - W + 1)} = \frac{\gamma}{m}$$

prior probability of a sequence containing a motif

prior probability that any position in a sequence is the start of a motif

E-step in the ZOOPS Model

$$Z_{i,j}^{(t)} = \frac{P(X_i \mid Z_{i,j} = 1, p^{(t-1)}) \lambda^{(t-1)}}{P(X_i \mid Q_i = 0, p^{(t-1)}) (1 - \gamma^{(t-1)})} + \sum_{k=1}^{m} P(X_i \mid Z_{i,k} = 1, p^{(t-1)}) \lambda^{(t-1)}}$$

• Q_i is a random variable for which Q_i = 1 if sequence X_i contains a motif, Q_i = 0 otherwise

$$Q_i = \sum_{j=1}^m Z_{i,j}$$

$$P(X_i \mid Q_i = 0, p^{(t-1)}) = \prod_{j=1}^{L} p_{c_j,0}^{(t-1)} \qquad P(Q_i = 0) = 1 - \gamma^{(t-1)}$$

M-step in the ZOOPS Model

- Update p same as before
- Update γ as follows:

$$\gamma^{(t)} \equiv m\lambda^{(t)} = \frac{1}{n} \sum_{i=1}^{n} Q_i^{(t)}$$

Extensions to the Basic EM Approach in MEME

- Varying the approach (TCM model) to assume zero or <u>more</u> motif occurrences per sequence
- Choosing the width of the motif
- Finding multiple motifs in a group of sequences
- ✓ Choosing good starting points for the parameters
- ✓ Using background knowledge to bias the parameters

Starting Points in MEME

- EM is susceptible to local maxima, so it's a good idea to try multiple starting points
- Insight: motif must be similar to some subsequence in data set
- For every distinct subsequence of length W in the training set
 - derive an initial p matrix from this subsequence
 - run EM for 1 iteration
- Choose motif model (i.e. p matrix) with highest likelihood
- Run EM to convergence

Using Subsequences as Starting Points for EM

- Set values matching letters in the subsequence to some value π
- Set other values to $(1-\pi)/(M-1)$ where M is the length of the alphabet
- Example: for the subsequence TAT with $\pi = 0.7$

$$p = \begin{bmatrix} 1 & 2 & 3 \\ A & 0.1 & 0.7 & 0.1 \\ C & 0.1 & 0.1 & 0.1 \\ G & 0.1 & 0.1 & 0.1 \\ T & 0.7 & 0.1 & 0.7 \end{bmatrix}$$
